Data Security Safeguards Reference

Shared clinical files in SharePoint and OneDrive - storing, sharing, and accessing

SCOPE Evaluate the configured control and the observed evidence separately. Microsoft 365 service encryption does not make an over-broad sharing link acceptable.

1. Storing

- Confirm the file is in an approved Microsoft 365 tenant, site, library, and retention context.
- Record the service encryption posture. SharePoint and OneDrive use disk-level and per-file encryption at rest.
- Check sensitivity-label, retention, or data-loss-prevention requirements specified by organizational policy; do not invent a label requirement when none is documented.

2. Sharing

- Record link type: Anyone, People in the organization, People with existing access, or Specific people.
- Record external recipients, expiration, password or verification controls where available, and whether the link matches the site's sharing policy.
- Treat an Anyone link for clinical PHI as a governance finding under this training baseline; do not change it unless authorized.

3. Accessing

- Review direct permissions, group membership, guest access, and inherited permissions.
- Use Microsoft Purview audit events to document sharing and file activity within the available retention window.
- A FileAccessed event establishes that the service recorded activity for an identity/session; it does not by itself establish the human actor or HIPAA breach status.

Finding record

Field	Required entry
Control expected	Named organizational baseline or policy
Observed state	Exact portal, configuration, or audit value
Outcome	Pass, Fail, or Review
Evidence	Record/event ID and timestamp
Routing	Information Governance; SOC; Privacy Office; or not triggered
Action boundary	No autonomous permission or sharing change
